RSA digital signatures

Hash-then-invert paradigm

# Syntax of digital signature schemes

## Syntax

A digital signature scheme  $DS = (KG, Sign, VF)$  is a triple of algorithms.

alg	input	output	notation	maybe randomized?	maybe stateful?
$\mathcal{K}$	-	key $pk, sk$	$(pk, sk) \xleftarrow{\$} KG$	yes	no
$Sign$	$(pk, sk) \in Keys(DS)$ $M \in \{0, 1\}^*$	signature $\sigma \in \{0, 1\}^* \cup \{\perp\}$	$\sigma \xleftarrow{\$} Sign_{sk}(M)$	yes	yes
$VF$	$(pk, sk) \in Keys(DS)$ $M, \sigma \in \{0, 1\}^*$	message $b \in \{0, 1\}$	$M \leftarrow VF_{pk}(M, \sigma)$	no	no

## Correctness

For all  $(pk, sk) \in Keys(DS)$ ,  $M \in \{0, 1\}^*$ ,

$$\Pr \left[ \sigma = \perp \text{ OR } VF_{pk}(M, \sigma) = 1 : \sigma \xleftarrow{\$} Sign_{sk}(M) \right] = 1 .$$

# Observations

1. Even the receiver cannot forge.
2. The verifier does not need to have any secrets.
3. For this to work, the verifier  $VF$  must have authentic  $pk$ !
4. Usage of keys is the mirror image of that of asymmetric encryption.

# Outline

Syntax of digital signature schemes

Security Definitions of digital signature schemes

RSA digital signatures

Hash-then-invert paradigm

# Unforgeability against CMA

Idea: Same as *MAC* except we give the forger the public key.

Let  $DS = (KG, \text{Sign}, \text{VF})$  be a DS scheme, and let  $A$  be an adversary.

<p>Subroutine Initialize</p> $b \xleftarrow{\$} \{0, 1\}; (pk, sk) \xleftarrow{\$} KG$ $S \leftarrow \emptyset$ <p>Return <math>pk</math></p> <p>Subroutine Sign(<math>M</math>)</p> $\sigma \xleftarrow{\$} \text{Sign}_{sk}(M)$ $S \leftarrow S \cup \{M\}$ <p>Return <math>\sigma</math></p> <p>Subroutine Finalize(<math>M, \sigma</math>)</p> $d \leftarrow \text{VF}(pk, M, \sigma)$ <p>Return <math>(d = 1 \wedge M \notin S)</math></p>	<p>Experiment <math>\mathbf{Exp}_{DS}^{\text{wuf-cma}}(A)</math></p> $pk \xleftarrow{\$} \text{Initialize}$ $(M, \sigma) \xleftarrow{\$} A^{\text{Sign}}(pk)$ <p>Return Finalize(<math>M, \sigma</math>)</p>
---	--

**wuf-cma advantage** of  $A$  mounting a CMA against  $DS$ :

$$\mathbf{Adv}_{DS}^{\text{wuf-cma}}(A) = \Pr \left[ \mathbf{Exp}_{DS}^{\text{wuf-cma}}(A) \Rightarrow \text{true} \right] .$$

# Digital Signatures: observations about security definition

## observations

1. for MAC, we give  $A$  both  $MAC_K(\cdot)$  and  $VF_K(\cdot, \cdot)$
2. resources :
  - ▶  $t$  = running time
  - ▶  $\mu$  = sum of lengths of oracle queries plus length of message in forgery
  - ▶  $q$  = number of queries to signing oracle.

# Outline

Syntax of digital signature schemes

Security Definitions of digital signature schemes

**RSA digital signatures**

Hash-then-invert paradigm

# RSA trapdoor signatures

Key generation : use  $K_{rsa} \rightarrow (N, e), (N, p, q, d)$  such that

$$ed \equiv 1 \pmod{\phi(N)}$$

$$e, d \in \mathbf{Z}_{\phi(N)}^*$$

$$N = p \cdot q$$

We know

1.  $RSA_{N,e}(\cdot)$  is easy
2.  $RSA_{N,d} = RSA_{N,e}^{-1}$
3. without  $d$ ,  $RSA_{N,e}^{-1}$  is hard

So to sign  $M$  : assume  $M \in \mathbf{Z}_N^*$   
 $\sigma \leftarrow RSA_{N,d}(M)$  [invert RSA on point  $M$ ]

## Scheme: textbook RSA signature

$Sign_{N,p,q,d}(M)$	$VF_{N,e}(M, x)$
If $M \notin \mathbf{Z}_N^*$ then $\perp$	If $(M \notin \mathbf{Z}_N^* \text{ or } x \notin \mathbf{Z}_N^*)$ then return 0
$x \leftarrow M^d \bmod N$	If $M = x^e \bmod N$ then return 1 else return 0
Return $x$	

Above, notice

1. *Sign* is deterministic and stateless
2.  $MsgSp(N, e) = \mathbf{Z}_N^*$
3. correctness condition : pass since  $RSA_{N,e}^{-1} = RSA_{N,d}$   
So  $x = M^d$  and  $x^e = M^{ed} = M$  ok

BUT Textbook RSA signature scheme is insecure!

# Breaking textbook RSA signature scheme

## Forger F1

idea: just outputs  $(1, 1)$

$VF_pk(1, 1)$  : if  $1 = 1^e \bmod N$  then return 1 else return 0

## Forger F2

idea: just pick  $x$  first, then compute the message  $M$

$F^{Sign_s k(\cdot)}(N, e)$

$x \xleftarrow{\$} \mathbf{Z}_N^*$

$M \leftarrow x^e \bmod N$

return  $(M, x)$

The verification algorithm  $VF$  will check whether  $M = x^e$ .

So  $VF$  returns 1.

# Breaking textbook RSA signature scheme (cont.)

## Forger F3

We can even forge any given message  $M$ !

$F^{Signsk(\cdot)}(N, e) :$

$$M_1 \xleftarrow{\$} \mathbf{Z}_N^* - \{1, M\}$$

$$M_2 \leftarrow MM_1^{-1} \bmod N$$

$$x_1 \leftarrow Signsk(M_1); x_2 \leftarrow Signsk(M_2)$$

$$x \leftarrow x_1 x_2 \bmod N$$

Return  $(M, x)$

## Bottom line

There's more to signatures than one-wayness of the underlying function!

# Observations

- ▶ From attacks we have seen, RSA function is **homomorphic**, i.e.

$$M^d = M_1^d M_2^d \text{ when } M = M_1 M_2$$

- ▶ Also, messages usually aren't group elements.
- ▶ To deal with these problems, we add a pre-processing step:  
Hash messages into  $\mathbf{Z}_N^*$  first.

# Outline

Syntax of digital signature schemes

Security Definitions of digital signature schemes

RSA digital signatures

Hash-then-invert paradigm

# Hash-then-invert paradigm

## scheme

Let  $K_{rsa}$  be an RSA generator with security parameter  $k$ .

Let  $Keys$  be the set of all moduli  $N$  that can be output by  $K_{rsa}$ .

Let  $Hash$  be a family of functions whose key space is  $Keys$  and  $\forall N \in Keys, Hash_N : \{0, 1\}^* \rightarrow \mathbf{Z}_N^*$ .

Let  $DS = (K_{rsa}, Sign, VF)$  be the digital signature scheme defined as

$Sign_{N,p,q,d}(M)$	$VF_{N,e}(M, x)$
$y \leftarrow Hash_N(M)$	$y \leftarrow Hash_N(M)$
$x \leftarrow y^d \bmod N$	$y' \leftarrow x^e \bmod N$
Return $x$	If $y = y'$ then return 1 else return 0

## How this scheme prevents attacks we have seen

### Recall Forger F1

idea: just outputs  $(1, 1)$

$VF_p k(1, 1)$  : if  $1 = 1^e \bmod N$  then return 1 else return 0

This works when  $Hash_N(1) \equiv 1^e \pmod{N}$ .

So we make sure that  $Hash_N(1) \not\equiv 1 \pmod{N}$ .

## How this scheme prevents attacks we have seen (cont.)

### Recall Forger F2

idea: just pick  $x$  first, then compute the message  $M$

$F^{Signsk(\cdot)}(N, e)$

$$x \xleftarrow{\$} \mathbf{Z}_N^*$$

$$M \leftarrow x^e \bmod N$$

return  $(M, x)$

For this to work, need  $M$  such that

$$Hash_N(M) \equiv x^e \pmod{N}$$

If *Hash* is “good,” it is hard to find such  $M$  that works.

## How this scheme prevents attacks we have seen (cont.)

### Recall Forger F3

We can even forge any given message  $M$ !

$F^{Sign_s k(\cdot)}(N, e) :$

$$M_1 \xleftarrow{\$} \mathbf{Z}_N^* - \{1, M\}$$

$$M_2 \leftarrow MM_1^{-1} \bmod N$$

$$x_1 \leftarrow Sign_s k(M_1); x_2 \leftarrow Sign_s k(M_2)$$

$$x \leftarrow x_1 x_2 \bmod N$$

Return  $(M, x)$

For this to work, we need

$$Hash_N(M_1) \cdot Hash_N(M_2) = Hash_N(M).$$

With a “good” hash function, this is rare.

## Bottom line

The hash function destroys the algebraic structure needed for the attacks to work.

**BUT** we also need **collision-resistance!**

Otherwise, we can attack.

# Attack against hash-then-invert scheme if *Hash* is bad

Suppose  $M_1, M_2$  be messages such that  $\exists N$ ,

$$\text{Hash}_N(M_1) \equiv \text{Hash}_N(M_2) \pmod{N}$$

Then, we can forge signing algorithm when modulus is  $N$  as follows:

## Forger $F$

Forger  $F^{\text{Sign}_{N,p,q,d}(\cdot)}(N, e) :$

$x_1 \leftarrow \text{Sign}_{N,p,q,d}(M_1)$

Return  $(M_2, x_1)$

Why does this work?

# Properties we need from *Hash* for the hash-then-invert paradigm

Necessary properties of Hash are at least

- ▶ destroy algebraic properties of the messages
- ▶ CR2-KK
- ▶ ???

We want **sufficient** conditions!

So we need provable security.

But first, let's consider some candidate hash functions.

# PKCS # 1 signature scheme

$$PKCS\text{-}Hash_N(M) = 0001\ FFFF \dots FF00 || h(M) \ [k \text{ bits}]$$

where  $h : \{0, 1\}^* \rightarrow \{0, 1\}^I$  and  $I \geq 128$  and  $h$  is assumed to be collision-resistant and  $k = |N|$ .

(In practice,  $h = SHA1(I = 160)$ . Used to be  $h = MD5(I = 128)$ .)

Notice :

1. First 4 bits are 0.  
So as an int,  $PKCS\text{-}Hash_N(\cdot) \leq N$
2. Most  $\#$ s between 1 and  $N$  are in  $\mathbf{Z}_N^*$ .  
(There are  $((p-1)(q-1))$  of them to be exact.)
3. If  $h$  is collision-resistant, then so is  $PKCS\text{-}Hash$ .

Would hash-then-invert with  $PKCS\text{-}Hash$  work ??

## PKCS-Hash

*PKCS-Hash* seems to destroy the algebraic properties of messages, i.e.

- ▶ hard to imagine

$$PKCS-Hash(M) = PKCS-Hash(M_1) \cdot PKCS-Hash(M_2)$$

- ▶ *PKCS-Hash* seems collision-resistant.
- ▶ BUT there's a cause of concern.

- ▶ We assume  $RSA_{N,e}$  is one-way.

- ▶ Q: what do we invert  $RSA_{N,e}$  on?

$Sign_{N,p,q,d}(M)$

$y \leftarrow PKCS-Hash_N(M)$

$x \leftarrow y^d \bmod N$

Return  $x$

A: We invert  $RSA_{N,e}$  on output points of *PKCS-Hash*.

# Security of PKCS # 1

Let  $S_N$  be the set of these points, i.e.

$$S_N = \{PKCS\text{-}Hash_N(M) : M \in \{0, 1\}^*\}.$$

So we want  $RSA_{N,e}$  to be hard to invert on points in  $S_N$ !

Let's compare the size of  $S_N$  to the size of  $\mathbf{Z}_N^*$ .

- ▶  $|S_N| \leq 2^{160}$   
[Front part is fixed and  
 $h : \{0, 1\}^* \rightarrow \{0, 1\}^l$  (for  $SHA1 : l = 160$ )]
- ▶ Recommended size for modulus is 1024.  
So  $|\mathbf{Z}_N^*| \simeq 2^{1023}$ .
- ▶ So  $\frac{|S_N|}{|\mathbf{Z}_N^*|} \leq \frac{2^{160}}{2^{1023}} = \frac{1}{2^{863}}$

$S_N$  is much much smaller than  $\mathbf{Z}_N^*$ !

Bottom line:  $RSA_{N,e}$  could be hard to invert in  $\mathbf{Z}_N^*$  but **easy** in  $S_N$ !

# Full-Domain-Hash (FDH) [BR96]

To address this problem, the hash should map inputs into the entire domain, i.e.,

## FDH

$$H : \{0, 1\}^* \rightarrow \mathbf{Z}_N^*$$

$$\text{Sign}_{N,p,q,d}^H(M)$$

$$x \leftarrow H(M)^d \bmod N$$

Return  $x$

$$\text{VF}_{N,e}^H(M, x)$$

If  $H(M) = x^e \bmod N$  then return 1

else return 0

FDH has been proven secure in the random oracle model.

# Schnorr signature scheme

Let  $G = \langle g \rangle$  be a cyclic group of order prime number  $m$ . Let  $H : \{0, 1\}^* \rightarrow \mathbf{Z}_m$  be a hash function.

**Alg** KG

$x \xleftarrow{\$} \mathbf{Z}_m$

$X \leftarrow g^x$

Return  $(X, x)$

**Alg**  $\text{Sign}_x^H(M)$

$r \xleftarrow{\$} \mathbf{Z}_m; R \leftarrow g^r$

$c \leftarrow H(R \| M)$

$s \leftarrow (r + cx) \bmod m$

Return  $(R, s)$

**Alg**  $\text{VF}_X(R, s)$

If  $(R \notin G)$  then return 0

$c \leftarrow H(R \| M)$

If  $(g^s = RX^c)$  then return 1

Return 0

Can you show that this scheme satisfies the correctness property?

# Security of Schnorr signature

If **DLP** is hard, then Schnorr signature scheme is **SUF-CMA** in the random oracle model.
